The slope m goes from about -2.47 to about -2.37, so $\alpha_m \approx 0.05$. Matches up well with what the fitting program returned.

The y-intercept b goes from about 6.82 to about 7.46, so $\alpha_b \approx 0.3$. Also matches up well with what the fitting program returned.

And the χ^2 ended up 5.6. There are 10 data points, so you would expect χ^2 to be something in

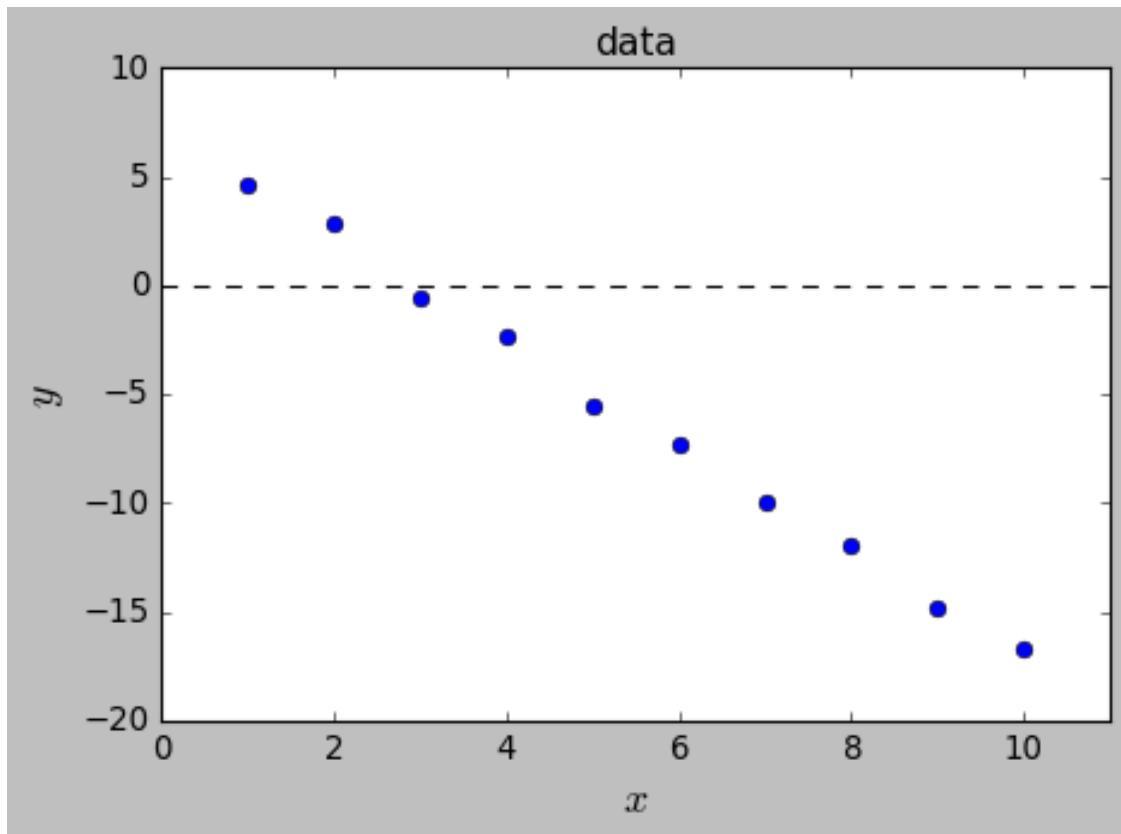

the range of 5 to 20. (Actually, this is too simplistic as we'll discuss in the next class. Really, there are 8 degrees of freedom, so you really should expect χ^2 to be around 8. And then the question is whether 5.6 is close enough to 8. It will turn out that the answer is "yes", although you will see better how to answer that more carefully in the next class.

So, yes, the fit seems reasonable.

1.2 1. Data Set 2

```
[9]: data = np.loadtxt("https://www.eg.bucknell.edu/~phys310/skills/data_analysis/

The slope m goes from about -2.427 to about -2.417, so $\alpha_m \approx 0.005$. Matches up well with what the fitting program returned. Of course, we already know that this fit is suspect, so we shouldn't be getting excited about small uncertainties here.

The y-intercept b goes from about 7.12 to about 7.19, so $\alpha_b \approx 0.03$. Also matches up well with what the fitting program returned.

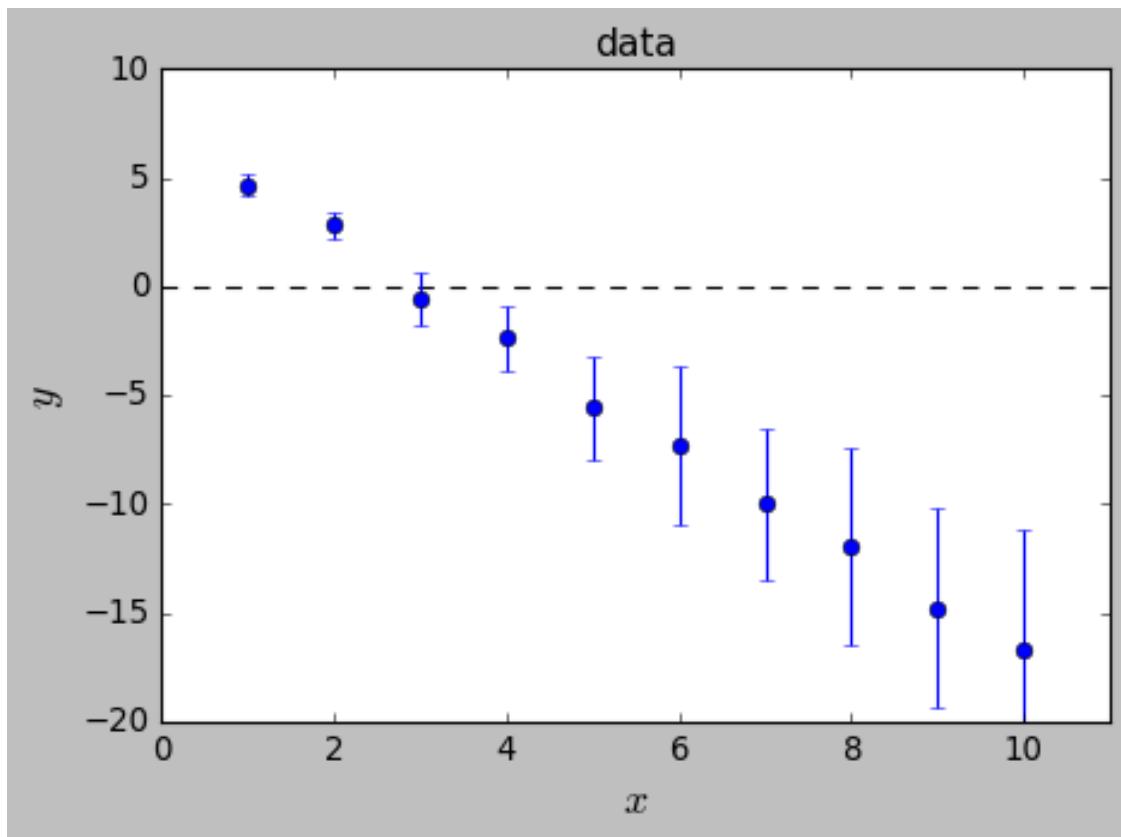

And χ^2 ended up 564. There are 10 data points, so you would expect χ^2 to be something in the range of 5 to 20. (Actually, this is too simplistic as we'll discuss in the next class. Really, there are 8 degrees of freedom, so you really should expect χ^2 to be around 8.) As we'll discuss in the next class, you can determine how unlikely this scenario is if the model is valid. But it's going to be awful – this χ^2 is a factor of 100 higher than should be expected.

So, no, this is not a reasonable fit to the data. Either (a) the model is invalid; or (b) the uncertainties in the data points were vastly underestimated.

1.3 1. Data Set 3

```
[14]: data = np.loadtxt("https://www.eg.bucknell.edu/~phys310/skills/data_analysis/

The slope m goes from about -2.65 to about -2.19, so $\alpha_m \approx 0.2$. Matches up well with what the fitting program returned.

The y-intercept b goes from about 6.7 to about 7.8, so $\alpha_b \approx 0.5$. Also matches up reasonably well with what the fitting program returned.

The χ^2 ended up 0.9. There are 10 data points, so you would expect χ^2 to be something in the range of 5 to 20. (Actually, this is too simplistic as we'll discuss in the next class. Really, there are 8 degrees of freedom, so you really should expect χ^2 to be around 8.) As we'll discuss in the next class, you can determine how unlikely this scenario is if the model is valid. But this isn't good – this χ^2 is a factor of 10 lower than should be expected.

So, there are problems here. This is exactly the kind of fit that people will often say that everything is fine because χ^2 is small. But it is *too* small. So, most likely, the uncertainties in the data points were overestimated.

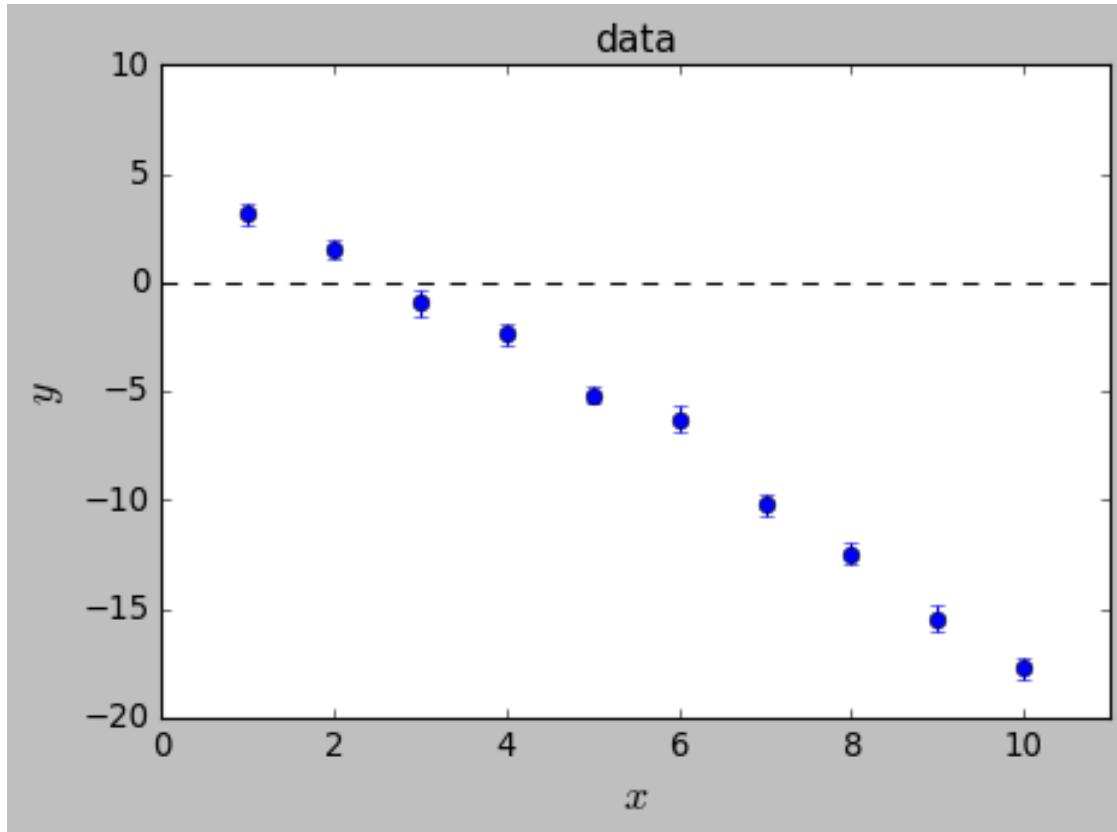

1.4 1. Data Set 4

```
[19]: data = np.loadtxt("https://www.eg.bucknell.edu/~phys310/skills/data_analysis/

The slope m goes from about -2.41 to about -2.30, so $\alpha_m \approx 0.05$. Matches up well with what the fitting program returned.

The y-intercept b goes from about 6.0 to about 6.7, so $\alpha_b \approx 0.3$. Also matches up reasonably well with what the fitting program returned.

The $\chi^2 = 13$, which is perfectly fine for a fit with 10 data points and 8 degrees of freedom. So, it's

hard to claim statistically that the linear model doesn't fit the data.

The problem with this data is easier to see in the residuals. The first three data points are high, then next three are low, and then they go high again. In other words, there is a pattern to the residuals that should make a linear fit questionable. A pattern like this suggests that a fit with a quadratic component (ax^2) might be appropriate.

The best you can say, I think, is that you should be suspicious of the linear model, and that you need more (or better) data. This is an example where simply looking at χ^2 is insufficient.

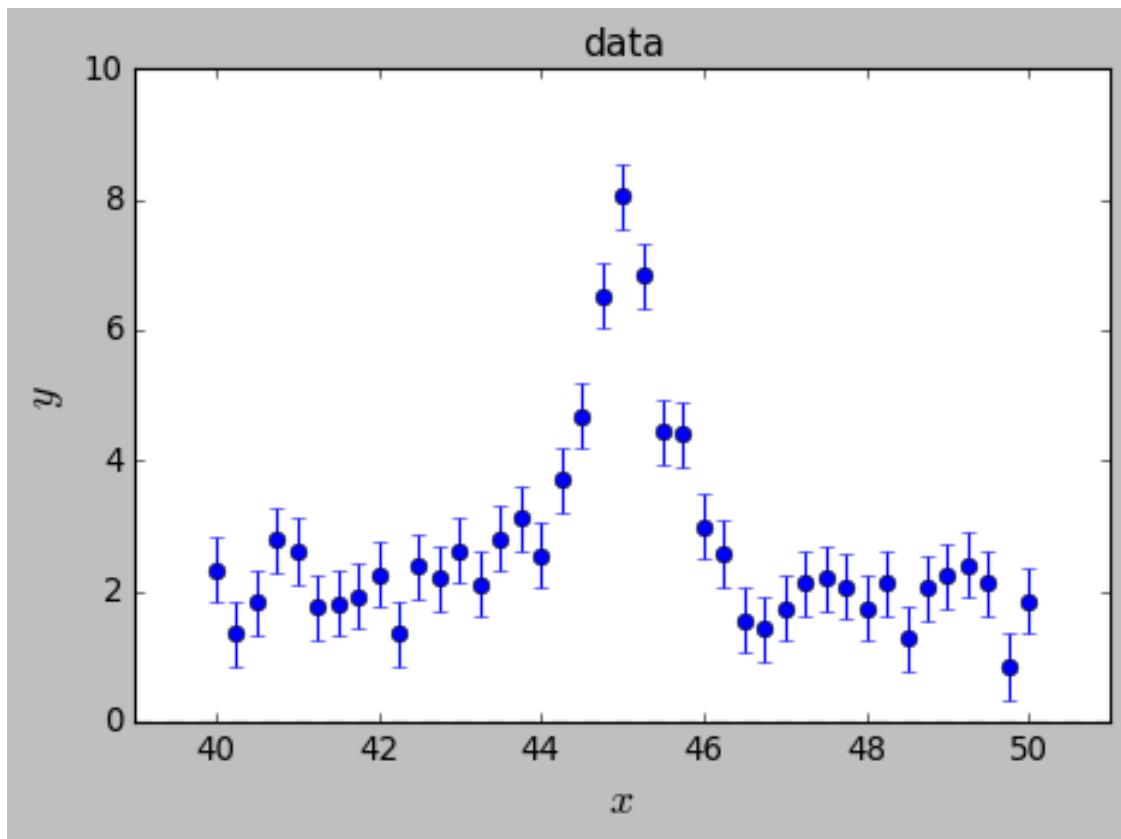

1.5 2. Fit_4 Data

The contour plots of the two sets of parameters show that the uncertainties are consistent with the fitting program. Particularly, the fitting program gave reasonable values for α_b and α_d , but may have slightly overestimated the uncertainties α_a and α_c . Overall, the values are reasonably the same to the first significant digit.

You might note that the b vs a contour plot is not tilted. This means a and b are very independent. The tilt of the d vs c contour plot indicates some correlation.
